- 1. (10 points) Let us consider four-lines geometry, it is a theory with undefined terms: "point", "line", "is on", and axioms:
 - 1. there exist exactly four lines,
 - 2. any two distinct lines have exactly one point on both of them, and
 - 3. each point is on exactly two lines.

Show that every line has exactly three points on it. (Be careful with the terms you use and axioms you use.)

Solution: Lets denote the lines as l_1, \ldots, l_4 (all of them exist and different by Axiom 1). Due to symmetry of the problem it is enough to prove that l_4 has exactly three points on it.

Let p_i $(1 \le i \le 3)$ be the point that is on l_i and l_4 (they exist by Axiom 2). Let us now prove that p_1 , p_2 , and p_3 are all different. Assume that $p_i = p_j$ for $i \ne j$ $(1 \le i, j \le 3)$ for the sake of contradiction. In this case p_i is on l_i , l_j , and l_4 which contradicts Axiom 3.

Let us now prove that there are no other points on l_4 . Assume that it is not true and there is p_4 in addition to p_1 , p_2 , and p_3 on l_4 . By Axiom 3, there is i $(1 \le i \le 3)$ such that p_4 is on l_i . Hence, p_i and p_4 are on l_i which contradicts to Axiom 2.

2. (10 points) In Euclidean (standard) geometry, prove: If two lines share a common perpendicular, then the lines are parallel. (You do not need to use axioms of Euclidean geometry in this exercise, you can use all the standard knowledge about geometry.)

Solution: Let us denote by AB the common perpendicular. Assume that the lines are not parallel (note that these lines are different) i.e. that there is an intersection C of these lines.

Note that the angles CAB and CBA are right, hence, the angle ACB is equal to 0 degrees. So the lines are the same, which is a contradiction.

Hence, the assumption was incorrect i.e. the lines are parallel.
